Feb 2 , 2015

# Algorithm for Testing Lossless Joins

*Input:* Relation schema  $R = \{A_1, A_2, \dots, A_n\}$ , a set of functional dependencies  $F$  and a decomposition scheme  $\rho = (R_1, R_2, \dots, R_k)$ .

*Output:* A decision whether  $\rho$  is a lossless join decomposition under  $F$ .

# Lossless testing algorithm

1. Construct a *table* with  $n$  columns and  $k$  rows.  
Column  $j$  corresponds to  $A_j$  and row  $i$  corresponds to relation  $R_i$ .
2. If  $A_j \in R_i$ , put the symbol  $a_j$  in  $(i, j)$  position.  
Otherwise, put the symbol  $b_{ij}$  in  $(i, j)$  position.
3. **repeat**
4.   **for** each dependency  $X \rightarrow Y$  in  $F$  **do**
5.     **if** there are two (or more) rows that agree in all the columns  
      for the attributes of  $X$
6.       equate the symbols of those rows for the attributes of  $Y$  as follows  
        **if** one of the symbols is  $a_j$ , make the other to be  $a_j$ .  
        **if** the symbols are  $b_{ij}, b_{lj}$ , make them both  
           $b_{ij}$  or  $b_{lj}$  arbitrarily.
7.   **until** there is no change to the table.
8.   **if** there is some row that is  $a_1, \dots, a_k$ , then the join is lossless  
    **else** it is lossy.

## Example

- Consider the example schema  $Suppliers(S, A, I, P)$  with functional dependencies  $S \rightarrow A$  and  $SI \rightarrow P$ .
- Initial table created is:

	S	A	I	P
SA	$a_1$	$a_2$	$b_{13}$	$b_{14}$
SIP	$a_1$	$b_{12}$	$a_3$	$a_4$

- Consider dependency  $S \rightarrow A$ . Equate  $a_2$  with  $b_{12}$ . This gives

	S	A	I	P
SA	$a_1$	$a_2$	$b_{13}$	$b_{14}$
SIP	$a_1$	$a_2$	$a_3$	$a_4$

- Second row is all  $a$ 's. Decomposition is lossless join.

## Example 2

- $R = \{A, B, C, D, E\}$ . Functional dependencies are

$$A \rightarrow C$$

$$DE \rightarrow C$$

$$B \rightarrow C$$

$$CE \rightarrow A$$

$$C \rightarrow D$$

Decomposition  $R_1 = AD, R_2 = AB, R_3 = BE, R_4 = CDE, R_5 = AE$ .

- Initial table:

	<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>	<i>E</i>
$R_1(AD)$	$a_1$	$b_{12}$	$b_{13}$	$a_4$	$b_{15}$
$R_2(AB)$	$a_1$	$a_2$	$b_{23}$	$b_{24}$	$b_{25}$
$R_3(BE)$	$b_{31}$	$a_2$	$b_{33}$	$b_{34}$	$a_5$
$R_4(CDE)$	$b_{41}$	$b_{42}$	$a_3$	$a_4$	$a_5$
$R_5(AE)$	$a_1$	$b_{52}$	$b_{53}$	$b_{54}$	$a_5$

- Apply  $A \rightarrow C$ . Rows 1,2 and 5 have  $a_1$  in column *A*. So equate  $b_{13}$ ,  $b_{23}$  and  $b_{53}$  to say  $b_{13}$ .

## Example ...

$$A \rightarrow C$$

$$DE \rightarrow C$$

$$B \rightarrow C$$

$$CE \rightarrow A$$

$$C \rightarrow D$$

	<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>	<i>E</i>
$R_1(AD)$	$a_1$	$b_{12}$	$b_{13}$	$a_4$	$b_{15}$
$R_2(AB)$	$a_1$	$a_2$	$b_{13}$	$b_{24}$	$b_{25}$
$R_3(BE)$	$b_{31}$	$a_2$	$b_{33}$	$b_{34}$	$a_5$
$R_4(CDE)$	$b_{41}$	$b_{42}$	$a_3$	$a_4$	$a_5$
$R_5(AE)$	$a_1$	$b_{52}$	$b_{13}$	$b_{54}$	$a_5$

- Apply  $B \rightarrow C$ . Equate  $b_{13}$  and  $b_{33}$ .

## Example ....

$$A \rightarrow C$$

$$DE \rightarrow C$$

$$B \rightarrow C$$

$$CE \rightarrow A$$

$$C \rightarrow D$$

	<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>	<i>E</i>
$R_1(AD)$	$a_1$	$b_{12}$	$b_{13}$	$a_4$	$b_{15}$
$R_2(AB)$	$a_1$	$a_2$	$b_{13}$	$b_{24}$	$b_{25}$
$R_3(BE)$	$b_{31}$	$a_2$	$b_{13}$	$b_{34}$	$a_5$
$R_4(CDE)$	$b_{41}$	$b_{42}$	$a_3$	$a_4$	$a_5$
$R_5(AE)$	$a_1$	$b_{52}$	$b_{13}$	$b_{54}$	$a_5$

- Apply  $C \rightarrow D$ . Rows 1,2,3 and 5 have  $b_{13}$  in column  $C$ . We equate the values  $a_4$ ,  $b_{24}$ ,  $b_{34}$  and  $b_{54}$  to  $a_4$ .

$$A \rightarrow C$$

$$DE \rightarrow C$$

$$B \rightarrow C$$

$$CE \rightarrow A$$

$$C \rightarrow D$$

	<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>	<i>E</i>
$R_1(AD)$	$a_1$	$b_{12}$	$b_{13}$	$a_4$	$b_{15}$
$R_2(AB)$	$a_1$	$a_2$	$b_{13}$	$a_4$	$b_{25}$
$R_3(BE)$	$b_{31}$	$a_2$	$b_{13}$	$a_4$	$a_5$
$R_4(CDE)$	$b_{41}$	$b_{42}$	$a_3$	$a_4$	$a_5$
$R_5(AE)$	$a_1$	$b_{52}$	$b_{13}$	$a_4$	$a_5$

- Now apply  $DE \rightarrow C$ . Rows 4 and 5 are equal on  $DE$  columns. Equate  $a_3$  with  $b_{53}$ .

	<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>	<i>E</i>
$R_1(AD)$	$a_1$	$b_{12}$	$a_3$	$a_4$	$b_{15}$
$R_2(AB)$	$a_1$	$a_2$	$a_3$	$a_4$	$b_{25}$
$R_3(BE)$	$b_{31}$	$a_2$	$a_3$	$a_4$	$a_5$
$R_4(CDE)$	$b_{41}$	$b_{42}$	$a_3$	$a_4$	$a_5$
$R_5(AE)$	$a_1$	$b_{52}$	$a_3$	$a_4$	$a_5$

- Now apply  $CE \rightarrow A$ . Rows 3, 4 and 5 are equal on  $CE$  columns. Equate  $a_1$  with  $b_{31}$  and  $b_{41}$ .

$$A \rightarrow C$$

$$DE \rightarrow C$$

$$B \rightarrow C$$

$$CE \rightarrow A$$

$$C \rightarrow D$$

	<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>	<i>E</i>
$R_1(AD)$	$a_1$	$b_{12}$	$a_3$	$a_4$	$b_{15}$
$R_2(AB)$	$a_1$	$a_2$	$a_3$	$a_4$	$b_{25}$
$R_3(BE)$	$a_1$	$a_2$	$a_3$	$a_4$	$a_5$
$R_4(CDE)$	$a_1$	$b_{42}$	$a_3$	$a_4$	$a_5$
$R_5(AE)$	$a_1$	$b_{52}$	$a_3$	$a_4$	$a_5$

- Row 3 is  $a_1, a_2, \dots, a_5$ . Hence decomposition has a lossless join.

# Proof of Correctness

- Suppose the final table produced by the algorithm does not have a row of  $a_1, a_2, \dots, a_n$ .
- View the final table as a relation  $r$  on schema  $R$ . The rows are tuples, and  $a_i$ 's and  $b_{ij}$ 's are symbols in the domain of  $A_j$ .
- Relation  $r$  satisfies the functional dependencies in  $F$  because, whenever a violation is found, the algorithm modifies the table accordingly (by equating symbols).

# Proof ...

- Claim:  $r \neq m_\rho(r)$ .
- For each  $r_i(R)$ , there is a tuple  $t_i \in r$  such that  $t_i[R_i]$  is all  $a$ 's.
- So the join of  $\pi_{R_i}(r)$ 's contains the tuple with all  $a$ 's.
- But  $(a_1, \dots, a_k) \notin r$ . Hence  $r \neq m_\rho(r)$ .
- Hence the decomposition  $\rho$  is not a lossless join.

# Proof of Converse

- Conversely, suppose that the final table has a row with all  $a$ 's.
- Consider the query

$$\{(a_1, \dots, a_n) \mid (\exists b_{11}) \dots (\exists b_{kn})(w_1 \in r \wedge \dots \wedge w_k \in r)\}$$

where  $w_i$  is the  $i$ th row of the initial table.

- View the table as shorthand for this query.
- Query defines  $m_\rho$  since  $m_\rho(r)$  contains an arbitrary tuples  $a_1, \dots, a_n$  iff for each  $i$ ,  $r$  contains a tuple with  $a$ 's in the attributes of  $R_i$  and arbitrary values in the other attributes.

$$\{a_1, \dots, a_n \mid (\exists b_{11}) \dots (\exists b_{kn})(w_1 \in r \wedge \dots \wedge w_k \in r)\}$$

- Since we assume that any relation  $r$  to which the query can be applied satisfies the dependencies in  $F$ , hence
- hence the query is equivalent to a set of similar formulas with some of the  $a$ 's and/or  $b$ 's identified.
- The modifications made by the algorithm are such that the table is always a shorthand for some formula whose value on relation  $r$  is  $m_\rho(r)$  whenever  $r$  satisfies  $F$ . This can be proved by induction on the number of symbols identified.
- Since the final table contains a row of all  $a$ 's, the query for the final table is of the form

$$\{a_1, \dots, a_n \mid r(a_1, \dots, a_n) \wedge \dots\}$$

- This is a subset of  $r$ . But it is also  $m_\rho(r)$ . Hence  $m_\rho(r) \subset r$ .
- Hence, whenever  $r$  satisfies  $F$ ,  $r = m_\rho(r)$ , or, that the decomposition is lossless.

# Decomposition into two fragments

## Lemma

If  $\rho = (R_1, R_2)$  is a decomposition of  $R$  and  $F$  is the set of functional dependencies that hold on  $R$ , then,  $\rho$  is a lossless decomposition iff  $(R_1 \cap R_2) \rightarrow R_2 - R_1$  or  $(R_1 \cap R_2) \rightarrow R_1 - R_2$  holds in  $F^+$ .

- Consider the initial table used by the algorithm. Let  $|R_1 \cap R_2| = s$ ,  $|R_1 - R_2| = t$  and  $|R_2 - R_1| = u$ .

	$R_1 \cap R_2$				$R_1 - R_2$			$R_2 - R_1$		
row for $R_1$	$a_1$	$a_2$	$\dots$	$a_s$	$a_{s+1}$	$\dots$	$a_{s+t}$	$b_{s+t+1}$	$\dots$	$b_{s+t+u}$
row for $R_2$	$a_1$	$a_2$	$\dots$	$a_s$	$b_{s+1}$	$\dots$	$b_{s+t}$	$a_{s+t+1}$	$\dots$	$a_{s+t+u}$

	$R_1 \cap R_2$				$R_1 - R_2$			$R_2 - R_1$		
row for $R_1$	$a_1$	$a_2$	$\dots$	$a_s$	$a_{s+1}$	$\dots$	$a_{s+t}$	$b_{s+t+1}$	$\dots$	$b_{s+t+u}$
row for $R_2$	$a_1$	$a_2$	$\dots$	$a_s$	$b_{s+1}$	$\dots$	$b_{s+t}$	$a_{s+t+1}$	$\dots$	$a_{s+t+u}$

Step 1:

- Prove by induction on the number of symbols identified by algorithm that if some  $b_j$  corresponding to attribute  $A_j$  is equated with  $a_j$ , then,  $A_j \in (R_1 \cap R_2)^+$ .
- Base Case: Straightforward.
- Induction Case: Again, straightforward.

	$R_1 \cap R_2$				$R_1 - R_2$			$R_2 - R_1$		
row for $R_1$	$a_1$	$a_2$	$\dots$	$a_s$	$a_{s+1}$	$\dots$	$a_{s+t}$	$b_{1,s+t+1}$	$\dots$	$b_{1,s+t+u}$
row for $R_2$	$a_1$	$a_2$	$\dots$	$a_s$	$b_{2,s+1}$	$\dots$	$b_{2,s+t}$	$a_{s+t+1}$	$\dots$	$a_{s+t+u}$

Step 2:

- Suppose  $(R_1 \cap R_2) \rightarrow Y$  has a proof from  $F$  using Armstrong's Axioms.
- Then, using an induction on the number of steps in this proof, show that any  $b_j$ 's in the columns corresponding to  $Y$ 's are changed to  $a_j$ 's.

Combining Steps 1 and 2:

- Thus, the row corresponding to  $R_1$  is all  $a$ 's iff  $(R_2 - R_1) \subset (R_1 \cap R_2)^+$ .
- Similarly, the row corresponding to  $R_2$  is all  $a$ 's iff  $(R_1 - R_2) \subset (R_1 \cap R_2)^+$ .
- The lemma now follows.

# Example

Example 1.

- $R = ABC$ .  $F = \{A \rightarrow B\}$ .
- Consider  $\rho = (AB, AC)$ .
- Since,  $AB \cap AC = A$  and  $B = AB - AC$ , and  $A \rightarrow B$ , hence,
- decomposition is lossless under  $F$ .

## Example 2.

- $R = ABC$ ,  $F = \{A \rightarrow B\}$ .
- Consider  $\rho = (AB, BC)$ .
- So  $AB \cap BC = B$  and  $B^+ = B$ .
- So  $B$  does not determine either  $A$  (which is  $AB - BC$ ) or  $C$  (which is  $BC - AB$ ).
- Hence decomposition is not lossless.

$R$			$\pi_{A,B}(R)$		$\pi_{B,C}(R) :$		$\pi_{AB}(R) \bowtie \pi_{BC}(R)$		
$A$	$B$	$C$	$A$	$B$	$B$	$C$	$A$	$B$	$C$
$a_1$	$b$	$c_1$	$a_1$	$b$	$b$	$c_1$	$a_1$	$b$	$c_1$
$a_2$	$b$	$c_2$	$a_2$	$b$	$b$	$c_2$	$a_1$	$b$	$c_2$
							$a_2$	$b$	$c_1$
							$a_2$	$b$	$c_2$

# Decompositions that preserve Dependencies

- Decompositions should be lossless: so that the original relation can be recovered from its projections.
- Let  $R$  be a schema and  $\rho = (R_1, \dots, R_k)$  be a decomposition and  $F$  be the set of functional dependencies.
- The *projection* of  $F$  onto a set  $Z \subset R$  is the set of all dependencies  $X \rightarrow Y$  in  $F^+$  such that  $XY \subset Z$ . Denoted as

$$\pi_Z(F) = \{X \rightarrow Y \in F^+ \mid XY \subset Z\}$$

- $\rho$  is said to be dependency preserving if

$$\left( \bigcup_{i=1}^k \pi_{R_i}(F) \right) \text{ logically implies } F$$

or

$$F \subset \left( \bigcup_{i=1}^k \pi_{R_i}(F) \right)^+$$

# Why dependency preservation is useful?

- Dependencies in  $F$  are statements about integrity constraints on legal instances of the relation.
- If  $\rho$  has the loss join decomposition property, but is not dependency preserving, then,
- each update (insert, modify, delete) to one of the  $R_i$ 's would require a join to check that the functional dependencies are satisfied.

However,

- 1 Lossless join decomposition property is absolutely crucial.
- 2 Dependency preservation is desirable. If decomposition is not dependency preserving, then it increases the runtime overhead to check dependencies by having to compute joins.

## Example

- Consider schema  $R(\text{City}, \text{Street}, \text{Pincode})$  written as  $R(C, S, P)$ .
- Functional dependencies  $F$  are:

$$C, S \rightarrow P$$

$$P \rightarrow C$$

- Consider decomposition  $CSP$  into  $CP$  and  $SP$ .
- This is lossless since,  $CP \cap SP = P$  and  $P \rightarrow C$ , and  $C = CP - SP$ .
- This is not dependency preserving, since,
  - 1  $\pi_{CP}(F) = \{P \rightarrow C\} \cup \{\text{trivial dependencies}\}.$
  - 2  $\pi_{SP}(F) = \{\text{trivial dependencies}\}.$
  - 3 Hence  $CS \rightarrow P$  is lost.

## Example

S	P
100 M.G. Road	400001
100 M.G. Road	400002

C	P
Bombay	400001
Bombay	400002

- The dependency  $CS \rightarrow P$  is violated.

C	S	P
Bombay	100 M.G. Road	400001
Bombay	100 M.G. Road	400002

# Testing Preservation of Dependencies

- We now see an algorithm with the following input and output.
- *Input:* A decomposition  $\rho = (R_1, \dots, R_k)$  and a set of functional dependencies  $F$ .
- *Output:* A decision whether  $\rho$  preserves  $F$ .

## Method

- Let  $G$  be the union of the functional dependencies projected on the fragments that is

$$G = \bigcup_{i=1}^k \pi_{R_i}(F)$$

- Test whether  $G$  covers  $F$ , or equivalently,
- for every  $X \rightarrow Y$  in  $F$ ,  $Y \subset X_G^+$ .
- The key is to compute  $X^+$  without having  $G$  available explicitly.
- Trick: Repeatedly close  $X$  with respect to the projections of  $F$  on each of the  $R_i$ 's.

# Algorithm for testing dependency preservation

- Let  $R_i$  be one of the fragments.
- Given a subset  $Z \subset R$ , an  $R_i$ -operation on  $Z$  w.r.t.  $F$  is to replace  $Z$  by

$$Z := Z \cup ((Z \cap R_i)^+ \cap R_i)$$

where the closure is taken with respect to  $F$ .

- An  $R_i$ -operation adjoins to  $Z$  those attributes  $A \in R_i$  such that  $Z \cap R_i \rightarrow A$  holds in  $F^+$ .

# Computing $X_G^+$

Now we compute  $X_G^+$  as follows.

- 1 Start with  $X$ .
- 2 Run through each of the  $R_i$ 's and perform an  $R_i$ -operation on  $X$ .
- 3 If at some pass, none of the  $R_i$ -operations change  $X$ , then we terminate.
- 4 The resulting set is  $X^+$ .

## Algorithm for computing $X_G^+$

1.  $Z = X$
2. **while** changes to  $Z$  occur
3.     **for**  $i = 1$  to  $k$  **do**
4.          $Z = Z \cup ((Z \cap R_i)^+ \cap R_i)$

Algorithm for testing dependency preservation.

1. **for** each dependency  $X \rightarrow Y$  in  $F$  **do**
2.     compute  $X_G^+$  using above algorithm.
3.     **if**  $Y \not\subseteq X_G^+$  **return no**
4. **return yes**

## Example

- $R = (A, B, C, D)$ . Dependencies

$$A \rightarrow B$$

$$B \rightarrow C$$

$$C \rightarrow D$$

$$D \rightarrow A$$

- Decomposition

$$\{AB, BC, CD\}$$

- Is it dependency preserving?
- At first sight it seems that the dependency  $D \rightarrow A$  is lost but this is not true. Compute  $\{D\}_G^+$ , where  $G = (\pi_{AB}(F) \cup \pi_{BC}(F) \cup \pi_{CD}(F))$ .

$R = (A, B, C, D)$ . Dependencies

$$A \rightarrow B$$

$$B \rightarrow C$$

$$C \rightarrow D$$

$$D \rightarrow A$$

Decomposition  $\{AB, BC, CD\}$

- ① Initially  $Z = \{D\}$ .
- ②  $AB$ -operation on  $Z$ . This is  $D \cup ((D \cap AB)^+ \cap AB) = D \cup \phi = D$ .
- ③  $BC$ -operation on  $Z$  gives  $D$  (since  $Z \cap BC = \phi$ ).
- ④  $CD$ -operation on  $Z$  gives

$$Z = D \cup (D^+ \cap CD) = D \cup (ABCD \cap CD) = CD$$

- ⑤  $AB$ -operation on  $Z$  gives no change since  $CD \cap AB = \phi$ .
- ⑥  $BC$ -operation on  $Z$  gives

$$Z = CD \cup ((CD)^+ \cap (BC)) = CD \cup (ABCD \cap BC) = BCD$$

- ⑦  $CD$  operation gives no change.
- ⑧  $AB$ -operation gives  $Z = ABCD$ .
- ⑨ Hence  $D \rightarrow A$  is preserved.

# Correctness Proof: Outline

- Recall  $G = (\cup_{i=1}^k \pi_{R_i}(F))^+$ .
- Each time an attribute is added to  $Z$ , we are using a dependency of  $G$ .
- So if the algorithm says “yes”, it must be correct.
- Conversely, suppose  $X \rightarrow Y$  is in  $G^+$ .
- Then, there is a sequence of steps of the closure algorithm (covered earlier) to take the closure of  $X$  with respect to  $G$ , we eventually include all the attributes of  $Y$ .
- Each of these steps involves the application of a dependency in  $G$ , and so is a dependency in  $\pi_{R_i}(F)$  for some  $R_i$ .
- Suppose  $U \rightarrow V$  be one such dependency.
- By induction on the number of steps of the closure algorithm, we can show that eventually  $U$  becomes a subset of  $Z$  and then on the next pass, the  $R_i$ -operation will add  $V$  to  $Z$  (if they are not there already)

# Dependency Preserving Decomposition into 3NF

- We now give an algorithm to obtain a dependency preserving decomposition that is in 3NF.
- *Input:* Relation scheme  $R$  and set of functional dependencies  $F$  that forms a minimal cover (also called canonical cover).
- *Output:* A dependency-preserving decomposition of  $R$  such that each relation scheme is in 3NF with respect to the projection of  $F$  onto the scheme.
- For initial simplicity, assume that all *RHS* of dependencies in  $F$  are of the form  $X \rightarrow A$ , where,  $A$  is a single attribute.

# Dependency Preserving decomposition

## *Algorithm:*

- If there are any attributes not involved in any dependency of  $F$ , create a relation schema with these attributes.
- If one of the dependencies of  $F$  involves all the attributes of  $R$ , then output  $R$  and terminate.
- Otherwise, for each dependency of the form  $X \rightarrow A$ , create a fragment with schema  $XA$ .
- If there are multiple dependencies  $X \rightarrow A_1, X \rightarrow A_2, \dots, X \rightarrow A_n$  in  $F$ , then, combine these into the schema  $XA_1A_2 \dots A_n$  instead of  $XA_i$ ,  $i = 1, 2, \dots, n$ .

## Example

Schema is  $CTHRSG$ , where,  $C$  = course,  $T$  = teacher,  $H$  = hour,  $R$  = room,  $S$  = student and  $G$  = grade.

$F =$

$C \rightarrow T$

$HR \rightarrow C$

$HT \rightarrow R$

$CS \rightarrow G$

$HS \rightarrow R$

- $F$  is a minimal cover.
- Dependency preserving decomposition is therefore

$CT$	$HRC$	$HTR$
$CSG$	$HSR$	

- This is also a lossless decomposition, since  $HS$  is the only key.

# Correctness Proof

- Since the projected dependencies  $\bigcup_{i=1}^k \pi_{R_i}(F)$  covers  $F$ , dependencies are preserved.
- Suppose  $Y \rightarrow B$  is in the minimal cover and results in the fragment  $YB$ .
- We have to show that  $R_i = YB$  is in 3NF.
- Suppose  $X \rightarrow A$  is a dependency logically implied by  $F$  and holding on  $R_i = YB$  such that it violates 3NF.
- Then, either  $X$  is not a superkey for  $YB$  or  $A$  is not prime.
- We know that  $XA \subset YB$ .

# Correctness Proof

- What do we know?  $YB$  is a fragment with  $Y \rightarrow B$  being in minimal cover.
- $X \rightarrow A$  is logically implied by  $F$  and  $AX \subset YB$  and  $X$  is not a superkey and  $Y$  is not prime in  $YB$ .
- Two cases: Case (i)  $A = B$ , Case (2)  $A \neq B$ .
- Case 1:  $A = B$ . So  $X \subset Y$  and  $X \rightarrow B$ . By minimality of cover  $X = Y$ , otherwise,  $Y - X$  would be left-extraneous or redundant in the minimal cover (contradiction).
- Case 2:  $A \neq B$ . Since  $Y$  is a superkey for  $YB$ , there is a subset  $Z \subset Y$  that is a key for  $YB$ .
  - ①  $A \in Y$  and  $A \notin Z$  since  $A$  is non-prime.
  - ② Then,  $Z \rightarrow B$  can replace  $Y \rightarrow B$ , contradicting minimality of the cover.

# Lossless join, dependency preserving decompositions into 3NF

- Previous algorithm did not give guarantees about the decomposition being lossless.
- Following method finds a decomposition that is lossless join and dependency preserving and is in 3NF.

*Method:*

- 1 Let  $\rho$  be the 3NF decomposition of  $R$  constructed by the previous algorithm.
- 2 Let  $X$  be a key for  $R$ .
- 3 Return  $\rho \cup \{X\}$ .

# Proof of Correctness

- $X$  is in 3NF. Suppose  $Y \rightarrow A$  be a non-trivial dependency that holds in  $F$  and  $YA \subset X$ .
- Then,  $X - \{A\}$  is a key for  $X$  and hence for  $R$ , contradicting that  $X$  is a key.
- Hence there cannot be any non-trivial dependencies in  $X$ .

## Correctness Proof contd.

- To show that  $\rho$  has a lossless join property, apply the tabular test.
- We will show that the row corresponding to  $X$  becomes all  $a$ 's.
- Proof is by induction on the order of the attributes  $A_1, A_2, \dots, A_k$  in which the attributes of  $R - X$  are added to  $X^+$  by the algorithm for computing the closure.
- By induction on  $i$  that the column corresponding to  $A_i$  for the row  $X$  is set to  $a_i$ .
- Basis:  $i = 0$ . Then, all columns corresponding to attributes of  $X$  are set to  $a$ 's.

# Correctness Proof

- Assume the result for  $i - 1$ .
- Then,  $A_i$  is added to  $X^+$  due to some given functional dependency  $Y \rightarrow A_i$  where

$$Y \subseteq X \cup \{A_1, \dots, A_{i-1}\}$$

- Now,  $YA_i$  is in  $\rho$  and the rows of  $YA_i$  and  $X$  agree on  $Y$  – they are all  $a$ 's after the columns of  $X$ -row for  $A_1, \dots, A_{i-1}$  are made  $a$ 's (induction).
- Thus, in this step of the tabular algorithm, these rows are made to agree on  $A_i$ .
- Since the  $YA_i$  row has  $a_i$ , so must the  $X$ -row.
