Multivariate Normal Distribution I

• The pdf of multivariate normal random vector $\mathbf{X}' = [X_1, X_2, \dots, X_p]$ with mean μ and covariance matrix Σ is given by

$$f(\mathbf{x}) = rac{1}{(2\pi)^{rac{
ho}{2}} |\Sigma|^{rac{1}{2}}} e^{-rac{1}{2}(\mathbf{x}-\mu)'\Sigma^{-1}(\mathbf{x}-\mu)},$$

where
$$-\infty < x_i < \infty$$
.

• Notation $\mathbf{X} \sim N_p(\mu, \Sigma)$

Multivariate Normal Distribution II

Bivariate Normal Density

$$f(x_1, x_2) = \frac{e^{-\frac{1}{2(1-\rho_{12}^2)} \left[\left(\frac{x_1-\mu_1}{\sqrt{\sigma_{11}}} \right)^2 + \left(\frac{x_2-\mu_2}{\sqrt{\sigma_{22}}} \right)^2 - 2\rho_{12} \left(\frac{x_1-\mu_1}{\sqrt{\sigma_{11}}} \right) \left(\frac{x_2-\mu_2}{\sqrt{\sigma_{22}}} \right) \right]}}{2\pi \sqrt{\sigma_{11}\sigma_{22} (1-\rho_{12}^2)}}$$

• Figure 4.2 (Page 152)

Multivariate Normal Distribution III

- Observation
 - Contours of constant density for the p-dimensional normal distribution are ellipsoids defined by x such that

$$(\mathbf{x} - \mu)' \Sigma^{-1}(\mathbf{x} - \mu) = c^2.$$

- These ellipsoids are centerded at μ and have axes $\pm c\sqrt{\lambda_i}e_i$,
 - where $\Sigma e_i = \lambda_i e_i$, for i = 1, 2, ..., p.
- Example 4.2 (Page 154)
- Code 01

Properties of Multivariate Normal Distribution I

- Properties of Multivariate Normal Distribution
 - Linear combinations of the components of X are normally distributed.
 - All subsets of the components of X have a (multivariate) normal distribution.
 - Zero covariance implies that the corresponding components are independently distributed.
 - The conditional distributions of the components are (multivariate) normal.

Properties of Multivariate Normal Distribution II

Result 1:

- If **X** is distributed as $N_p(\mu, \Sigma)$, then any linear combination of variables $\mathbf{a}'\mathbf{X} = a_1X_1 + a_2X_2 + \ldots + a_pX_p$ is distributed as $N(a'\mu, a'\Sigma a)$.
- Also,if $\mathbf{a}'\mathbf{X}$ is distributed as $N(\mathbf{a}'\mu, \mathbf{a}'\Sigma\mathbf{a})$ for every \mathbf{a} , then \mathbf{X} must be $N_p(\mu, \Sigma)$.

Properties of Multivariate Normal Distribution III

- Result 2:
 - If **X** is distributed as $N_p(\mu, \Sigma)$, the *q* linear combinations

$$A\mathbf{X} = \begin{bmatrix} a_{11}X_1 + \ldots + a_{1p}X_p \\ a_{21}X_1 + \ldots + a_{2p}X_p \\ \vdots \\ a_{q1}X_1 + \ldots + a_{qp}X_p \end{bmatrix} = \begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_p \end{bmatrix} = \mathbf{Y}$$

are distributed as $N_q(A\mu, A\Sigma A')$.

- Sketch of proof: For any \mathbf{c} , $\mathbf{c}'\mathbf{Y} \sim N()$, as it is a linear combination of X_1, X_2, \dots, X_p .
- Also, **X** + **d**, where *d* is a vector of constants, is distributed as N_p(μ + d, Σ).

Properties of Multivariate Normal Distribution IV

- Result 3:
 - All subsets of X are normally distributed.
 - If we respectively partition ${\bf X}$, its mean vector μ , and its covariance matrix ${\bf \Sigma}$ as

$$\mathbf{X}_{p\times 1} = \begin{bmatrix} \mathbf{X}_{1q\times 1} \\ \mathbf{X}_{2(p-q)\times 1} \end{bmatrix}, \mu = \begin{bmatrix} \mu_{1q\times 1} \\ \mu_{2(p-q)\times 1} \end{bmatrix}$$

and

$$\Sigma_{p \times p} = \begin{bmatrix} \Sigma_{11q \times q} & \Sigma_{12q \times (p-q)} \\ \Sigma_{21(p-q) \times q} & \Sigma_{22(p-q) \times (p-q)} \end{bmatrix}$$

then X_1 is distributed as $N_q(\mu_1, \Sigma_{11})$.

Properties of Multivariate Normal Distribution V

Sketch of proof:
 For example if we are interested in the subset {X_k, X_l}, then choose the matrix A as in Result 2 as

$$A = \begin{bmatrix} 0 & 0 & \cdots & 0 & 0 \\ 0 & 1_{(k,k)} & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 1_{(l,l)} & 0 \\ 0 & 0 & \cdots & 0 & 0 \end{bmatrix}$$

Properties of Multivariate Normal Distribution VI

- Result 4:
 - If $\begin{bmatrix} X_1 \\ X_2 \end{bmatrix}$ is

$$N_{q_1+q_2}\left(egin{bmatrix} \mu_1 \ \mu_2 \end{bmatrix}, egin{bmatrix} \Sigma_{11} & \Sigma_{12} \ \Sigma_{21} & \Sigma_{22} \end{bmatrix}
ight),$$

then X₁ and X₂ are independent iff

$$\textit{Cov}(\boldsymbol{X_1},\boldsymbol{X_2}) = \boldsymbol{\Sigma_{12}} = 0.$$

Properties of Multivariate Normal Distribution VII

Sketch of proof: Joint density function

$$f(\mathbf{x}) = \frac{1}{(2\pi)^{\frac{D}{2}} |\Sigma|^{\frac{1}{2}}} e^{-\frac{1}{2}(\mathbf{x} - \mu)'\Sigma^{-1}(\mathbf{x} - \mu)}$$

$$= \frac{1}{(2\pi)^{\frac{Q_1 + Q_2}{2}} |\sum_{1}^{\Sigma_{11}} 0 - \sum_{22}^{0}|^{\frac{1}{2}}} e^{-\frac{1}{2} \begin{bmatrix} \mathbf{x}_1 - \mu_1 \\ \mathbf{x}_2 - \mu_2 \end{bmatrix}' \begin{bmatrix} \Sigma_{11} & 0 \\ 0 & \Sigma_{22} \end{bmatrix}^{-1} \begin{bmatrix} \mathbf{x}_1 - \mu_1 \\ \mathbf{x}_2 - \mu_2 \end{bmatrix}}$$

$$= \frac{1}{(2\pi)^{\frac{Q_1 + Q_2}{2}} |\Sigma_{11}|^{\frac{1}{2}} |\Sigma_{22}|^{\frac{1}{2}}} e^{-\frac{1}{2} \begin{bmatrix} \mathbf{x}_1 - \mu_1 \\ \mathbf{x}_2 - \mu_2 \end{bmatrix}} \begin{bmatrix} \Sigma_{11}^{-1} & 0 \\ 0 & \Sigma_{22}^{-1} \end{bmatrix} \begin{bmatrix} \mathbf{x}_1 - \mu_1 \\ \mathbf{x}_2 - \mu_2 \end{bmatrix}}$$

$$= \frac{1}{(2\pi)^{\frac{Q_1}{2}} |\Sigma_{11}|^{\frac{1}{2}}} e^{-\frac{1}{2}(\mathbf{x}_1 - \mu_1)'\Sigma_{11}^{-1}(\mathbf{x}_1 - \mu_1)} \frac{1}{(2\pi)^{\frac{Q_2}{2}} |\Sigma_{22}|^{\frac{1}{2}}} e^{-\frac{1}{2}(\mathbf{x}_2 - \mu_2)'\Sigma_{22}^{-1}(\mathbf{x}_2 - \mu_2)}$$

$$= f(\mathbf{x}_1) f(\mathbf{x}_2)$$

Properties of Multivariate Normal Distribution VIII

- Result 5:
 - Let $\mathbf{X} = \begin{bmatrix} \mathbf{X_1} \\ \mathbf{X_2} \end{bmatrix}$ be distributed as $N_p(\mu, \Sigma)$ with

$$\mu = \begin{bmatrix} \mu_{\mathbf{1}} \\ \mu_{\mathbf{2}} \end{bmatrix}, \Sigma = \begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix} \text{ and } |\Sigma_{22}| > 0.$$

Then the conditional distribution of $\mathbf{X_1},$ given that $\mathbf{X_2}=\mathbf{x_2},$ is normal and has

Mean =
$$\mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(\mathbf{x_2} - \mu_2)$$

and

Covariance
$$= \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}$$
.

Properties of Multivariate Normal Distribution IX

Sketch of the proof: Choose

$$A = \begin{bmatrix} I_{q_1 \times q_1} & -\Sigma_{12}\Sigma_{22}^{-1} \\ 0 & I_{q_2 \times q_2} \end{bmatrix}.$$

Now.

$$A(\mathbf{X} - \mu) = \begin{bmatrix} \mathbf{X}_1 - \mu_1 - \Sigma_{12}\Sigma_{22}^{-1}(\mathbf{X}_2 - \mu_2) \\ \mathbf{X}_2 - \mu_2 \end{bmatrix} \sim N_p \left(\mathbf{0}, \begin{bmatrix} \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21} & 0 \\ 0 & \Sigma_{22} \end{bmatrix} \right)$$

Thus.

$$\mathbf{X_1} - \mu_1 - \Sigma_{12}\Sigma_{22}^{-1}(\mathbf{X_2} - \mu_2) \sim \textit{N}_{\textit{q}_1}(\mathbf{0}, \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})$$

and it is independent of $\mathbf{X_2}$.

Hence, given $\mathbf{X_2} = \mathbf{x_2}$ for any $\mathbf{x_2}$,

$$\mathbf{X_1}|\mathbf{X_2} = \mathbf{x_2} \sim \textit{N}\left(\mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(\mathbf{x_2} - \mu_2), \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}\right)$$

Properties of Multivariate Normal Distribution X

- Result 6:
 - Let **X** be distributed as $N_p(\mu, \Sigma)$ with $|\Sigma| > 0$. Then
 - $(\mathbf{X} \mu)' \Sigma^{-1} (\mathbf{X} \mu)$ is distributed as χ_p^2 .
 - The $N_{\rho}(\mu, \Sigma)$ distribution assigns probability $1-\alpha$ to the solid ellipsoid $\{\mathbf{x}: (\mathbf{X}-\mu)'\Sigma^{-1}(\mathbf{X}-\mu) \leq \chi^2_{\rho}(\alpha)\}$ where denotes the upper (100α) th percentile of the χ^2_{ρ} distribution.

Properties of Multivariate Normal Distribution XI

Sketch of proof:

Choose
$$A = \begin{bmatrix} \frac{1}{\sqrt{\lambda_1}} e_1' \\ \vdots \\ \frac{1}{\sqrt{\lambda_D}} e_D' \end{bmatrix}$$
, where $(\lambda_i, \mathbf{e}_i)s$ are eigen-value and eigen-vector pairs of $\Sigma = \sum_{i=1}^p \lambda_i e_i e_i'$.

Now

$$\mathbf{Z} = A(\mathbf{X} - \mu) \sim N_p(\mathbf{0}, A\Sigma A' = I).$$

Thus,

$$\mathbf{Z}'\mathbf{Z} = (\mathbf{X} - \mu)'A'A(\mathbf{X} - \mu) = (\mathbf{X} - \mu)' \begin{bmatrix} \frac{1}{\sqrt{\lambda_1}} e_1 \cdots \frac{1}{\sqrt{\lambda_p}} e_p \end{bmatrix} \begin{bmatrix} \frac{1}{\sqrt{\lambda_1}} e_1' \\ \vdots \\ \frac{1}{\sqrt{\lambda_p}} e_p' \end{bmatrix} (\mathbf{X} - \mu)$$

$$= (\mathbf{X} - \mu)' \begin{bmatrix} \sum_{i=1}^{p} \frac{1}{\lambda_i} e_i e_i' \end{bmatrix} (\mathbf{X} - \mu) = (\mathbf{X} - \mu)' \Sigma^{-1} (\mathbf{X} - \mu) \sim \chi_p^2$$

Code02

Properties of Multivariate Normal Distribution XII

- Result 7:
 - Let $X_1, X_2, ..., X_n$ be mutually independent with X_j distributed as $N_p(\mu_j, \Sigma)$. Then

$$\mathbf{V}_1 = c_1 \mathbf{X}_1 + c_2 \mathbf{X}_2 + \ldots + c_n \mathbf{X}_n$$

is distributed as $N_p\left(\sum_{j=1}^n c_j \mu_j, \left(\sum_{j=1}^n c_j^2\right) \Sigma\right)$.

• Moreover, V_1 and $V_2 = b_1 X_1 + b_2 X_2 + ... + b_n X_n$ are jointly multivariate normal with covariance matrix

$$\begin{bmatrix} \boldsymbol{c}'\boldsymbol{c}\boldsymbol{\Sigma} & \boldsymbol{b}'\boldsymbol{c}\boldsymbol{\Sigma} \\ \boldsymbol{b}'\boldsymbol{c}\boldsymbol{\Sigma} & \boldsymbol{b}'\boldsymbol{b}\boldsymbol{\Sigma} \end{bmatrix}.$$

Consequently, V_1 and V_2 are independent if $\mathbf{b}'\mathbf{c} = 0$.

Sampling from Multivariate Normal Distribution I

- Let the sample size be n
- Samples are taken independently from a multivariate normal population with mean vector μ and covariance matrix Σ
- Likelihood function

$$f_{\mathbf{X}_{1},\mathbf{X}_{2},...,\mathbf{X}_{n}}(\mathbf{X}_{1},\mathbf{X}_{2},...,\mathbf{X}_{n}) = \prod_{j=1}^{n} \frac{1}{(2\pi)^{\frac{p}{2}}|\Sigma|^{\frac{1}{2}}} e^{-\frac{1}{2}(x_{j}-\mu)'\Sigma^{-1}(x_{j}-\mu)}$$

$$= \frac{-\frac{1}{2}\sum_{j=1}^{n} (x_{j}-\mu)'\Sigma^{-1}(x_{j}-\mu)}{(2\pi)^{\frac{np}{2}}|\Sigma|^{\frac{n}{2}}}$$

$$= L(\mu,\Sigma).$$

Sampling from Multivariate Normal Distribution II

- Result 8:
 - Let X_1, X_2, \dots, X_n be a random sample from a normal population with mean μ and covariance Σ . Then

$$\hat{\mu} = \bar{\mathbf{X}}$$
 and $\hat{\Sigma} = \frac{1}{n} \sum_{j=1}^{n} (\mathbf{X_j} - \bar{\mathbf{X}}) (\mathbf{X_j} - \bar{\mathbf{X}})' = \frac{n-1}{n} S$

are the *maximum likelihood estimator*s of μ and Σ , respectively.

Their observed values, $\bar{\mathbf{x}}$ and $\frac{1}{n}\sum_{j=1}^{n}(\mathbf{x_j}-\bar{\mathbf{x}})(\mathbf{x_j}-\bar{\mathbf{x}})'$, are called the maximum likelihood estimates of μ and Σ .

Sampling from Multivariate Normal Distribution III

Sketch of proof:

$$L(\mu, \Sigma) \propto \frac{1}{|\Sigma|^{n/2}} e^{-\frac{1}{2} \sum_{i=1}^{n} (\mathbf{x}_i - \mu)' \Sigma^{-1} (\mathbf{x}_i - \mu)}$$

Note

$$\begin{split} \sum_{i=1}^{n} (\mathbf{x}_{i} - \boldsymbol{\mu})' \boldsymbol{\Sigma}^{-1} (\mathbf{x}_{i} - \boldsymbol{\mu}) &= \sum_{i=1}^{n} (\mathbf{x}_{i} - \bar{\mathbf{x}} + \bar{\mathbf{x}} - \boldsymbol{\mu})' \boldsymbol{\Sigma}^{-1} (\mathbf{x}_{i} - \bar{\mathbf{x}} + \bar{\mathbf{x}} - \boldsymbol{\mu}) \\ &= \sum_{i=1}^{n} (\mathbf{x}_{i} - \bar{\mathbf{x}})' \boldsymbol{\Sigma}^{-1} (\mathbf{x}_{i} - \bar{\mathbf{x}}) + n(\bar{\mathbf{x}} - \boldsymbol{\mu})' \boldsymbol{\Sigma}^{-1} (\bar{\mathbf{x}} - \boldsymbol{\mu}), \end{split}$$

is minimized at $\mu = \bar{\mathbf{x}}$

Sampling from Multivariate Normal Distribution IV

Note

$$L(\mu = \bar{\mathbf{x}}, \Sigma) \propto \frac{1}{|\Sigma|^{n/2}} e^{-\frac{1}{2} \sum_{i=1}^{n} (\mathbf{x}_i - \bar{\mathbf{x}})' \Sigma^{-1} (\mathbf{x}_i - \bar{\mathbf{x}})} = \frac{1}{|\Sigma|^{n/2}} e^{-\frac{1}{2} tr \left[\Sigma^{-1} \sum_{i=1}^{n} (\mathbf{x}_i - \bar{\mathbf{x}}) (\mathbf{x}_i - \bar{\mathbf{x}})'\right]}.$$

Let,
$$B = \sum_{i=1}^{n} (\mathbf{x}_i - \bar{\mathbf{x}}) (\mathbf{x}_i - \bar{\mathbf{x}})'$$
.

Thus,
$$L(\mu = \bar{\mathbf{x}}, \Sigma) \propto \frac{1}{|\Sigma|^{n/2}} e^{-\frac{1}{2} tr(\Sigma^{-1} B)}$$
.

Let η_i s are eigenvalues of $B^{1/2}\Sigma^{-1}B^{1/2}$. Hence,

$$L(\mu = \bar{\mathbf{x}}, \Sigma) \propto \frac{1}{|\Sigma|^{n/2}} e^{-\frac{1}{2}tr(\Sigma^{-1}B)} = \frac{|B|^{n/4}|\Sigma|^{-n/2}|B|^{n/4}}{|B|^{n/2}} e^{-\frac{1}{2}tr(B^{1/2}\Sigma^{-1}B^{1/2})}$$

$$= \frac{|B^{1/2}\Sigma^{-1}B^{1/2}|^{\frac{n}{2}}}{|B|^{\frac{n}{2}}} e^{-\frac{1}{2}tr(B^{1/2}\Sigma^{-1}B^{1/2})}$$

$$= \frac{\left(\prod_{i=1}^{p} \eta_{i}\right)^{\frac{n}{2}}}{|B|^{\frac{n}{2}}} e^{-\frac{1}{2}\sum_{i=1}^{p} \eta_{i}} = \prod_{i=1}^{p} \eta_{i}^{\frac{n}{2}} e^{-\frac{\eta_{i}}{2}}$$

$$= \frac{\left(\prod_{i=1}^{p} \eta_{i}\right)^{\frac{n}{2}}}{|B|^{\frac{n}{2}}} e^{-\frac{1}{2}\sum_{i=1}^{p} \eta_{i}} = \prod_{i=1}^{p} \eta_{i}^{\frac{n}{2}} e^{-\frac{\eta_{i}}{2}}.$$

Since, $x^{n/2}e^{-x/2}$ is maximized at x = n.

Thus
$$\max(L(\bar{\mathbf{x}}, \Sigma)) = \frac{n^{np/2}e^{-np/2}}{|B|^{n/2}}$$
.

Now at $\Sigma = \frac{1}{n}B$, the $L\left(\bar{\mathbf{x}}, \Sigma = \frac{1}{n}B\right) \propto \frac{1}{\left|\frac{1}{n}B\right|^{n/2}}e^{-\frac{1}{2}tr\left(nB^{-1}B\right)} = \frac{\frac{np}{n^{\frac{n}{2}}}}{|B|^{n/2}}e^{-np/2}$, we achieve the maximum.

21/39

Sampling from Multivariate Normal Distribution V

Obsevation:

$$L(\hat{\mu}, \hat{\Sigma}) = \frac{1}{(2\pi)^{\frac{np}{2}}} e^{-\frac{np}{2}} \frac{1}{|\hat{\Sigma}|^{\frac{n}{2}}}$$

$$\propto \text{ (Generalized Variance)}^{-\frac{n}{2}},$$

since

$$|\hat{\Sigma}| = |S_n| = \left(\frac{n-1}{n}\right)^p |S|.$$

The Sampling Distribution of \bar{X} and S

- ullet Properties of \bar{X} and S
 - \bar{X} is distributed as

$$N_p\left(\mu,\frac{1}{n}\Sigma\right)$$

• (n-1)S is distributed as

$$W_{p,(n-1)} = \sum_{i=1}^{n-1} ZZ',$$

where $Z \sim N_p(0, \Sigma)$.

- Wishart random matrix of order $p \times p$ with n-1 d.f.
- \bar{X} and S are independent.

Large Sample Behavior of \bar{X} and S

- Large Sample Behavior of \bar{X} and S
 - (Law of large numbers). Let $X_1, X_2, ..., X_n$ be independent observations from a population with mean $E(X_i) = \mu$. Then

$$\bar{X} = \frac{X_1 + X_2 + \ldots + X_n}{n}$$

converges in probability to μ as n increases without bound.

- S converges to Σ in probability.
- (The central limit theorem). Let X_1, X_2, \ldots, X_n be independent observations from any population with mean μ and finite covariance Σ . Then

$$\sqrt{n}(\bar{X}-\mu)\sim N_p(0,\Sigma)$$

for large sample sizes. Here n should also be large relative to p.

• $n(\bar{X} - \mu)' S^{-1}(\bar{X} - \mu)$ is approximately χ_p^2 .

Assessing the Assumption of Normality I

- Most of the statistical techniques discussed, assume that each vector observation X_i comes from a multivariate normal distribution.
 - Do the marginal distributions of the elements of X appear to be normal?
 - Do the scatter plots of pairs of observations on different characteristics give the elliptical appearance expected from normal populations?

Assessing the Assumption of Normality II

- It has proved difficult to construct a "good" overall test of joint normality in more than two dimension.
 - It is possible, for example, to construct a nonnormal bivariate distribution with normal marginals.
 - For most practical work, one-dimensional and two-dimensional investigations are ordinarily sufficient

Assessing the Assumption of Normality III

- Evaluating the Normality of the Univariate Marginal Distributions.
 - **1** A univariate normal distribution assigns probability .683(.954) to the interval $(\mu_i 1(2)\sqrt{\sigma_{ii}}, \mu_i + 1(2)\sqrt{\sigma_{ii}})$.
 - Consequently, with a large sample size n, we expect the observed proportion of the observations lying in the interval $(\bar{x}_i 1(2)\sqrt{s_{ii}}, \bar{x}_i + 1(2)\sqrt{s_{ii}})$. to be about .683(.954).

Assessing the Assumption of Normality IV

Q-Q plot

- Let $x_{(1)}, x_{(2)}, \ldots, x_{(n)}$ represent these observations after they are ordered according to magnitude.
- For a standard normal distribution, the quantiles, $q_{(j)}$ are defined by the relation

$$\int_{-\infty}^{q(j)} \frac{\mathrm{e}^{-\frac{z^2}{2}}}{\sqrt{2\pi}} dz = \frac{j - .5}{n}.$$

• If the data arise from a normal distribution the pairs $(q_{(j)}, x_{(j)})$ will be approximately linearly related.

Example 4.9 (Page 179)

Assessing the Assumption of Normality V

- Evaluating the Normality of the Bivariate Distributions.
 - If the observations were generated from a multivariate normal distribution, each bivariate distribution would be normal.
 - Check the set of bivariate outcomes **x** such that $(x \mu)' \Sigma^{-1} (x \mu) \le \chi_2^2 (.5)$ has probability 0.5.
 - μ is replaced by \bar{x} and Σ^{-1} is replaced by S^{-1} .

Assessing the Assumption of Normality VI

- ② More formal method for judging the joint normality of a data set is based on squared generalized distance $d_j^2 = (x_j \bar{x})' S^{-1}(x_j \bar{x})$, where x_i s are sample observations.
 - When the parent population is multivariate normal and both n and n-p are large each of the squared distances $d_1^2, d_2^2, \ldots, d_n^2$ should behave like a chi-square random variable.
 - The resulting plot is called chi-square plot or gamma plot.
 - Note: It can be used for any $p \ge 2$.

Assessing the Assumption of Normality VII

- Constructing chi-square plot
 - \bullet Order the squared distance $\textit{d}_{(1)}^2, \textit{d}_{(2)}^2, \dots, \textit{d}_{(n)}^2$
 - Graph the pairs $(q_{c,p}\frac{(j-.5)}{n}, d_{(j)}^2)$, where $q_{c,p}(\frac{j-.5}{n})$ is the 100(j-.5)/n quantile of the chi-square distribution with p degrees of freedom.
- The plot should resemble a straight line through the origin having slop 1.
- One or two points far above the line indicate large distances, or outlying observations, that merit further attention.
 Example 4.13 (Page 184)

Detecting Outliers and Cleaning Data I

- Most data sets contain one or few unusual observations that do not seem to belong to the pattern of variability produced by other obseravtions.
- Outliers are not wrong numbers, they need further investigations.

Detecting Outliers and Cleaning Data II

- Methods of detecting outliers
 - Make a dot plot for each variable.
 - Calculate the standardized values $z_{jk} = \frac{x_{jk} \bar{x_k}}{\sqrt{s_{kk}}}$, for j = 1, ..., n and k = 1, ..., p.
 - Examine these standardized values for large and small values.

Figure 4.10 (Page 188)

- Make a scatter plot for each pair of variables.
 - Calculate the generalized sqaured distance $(x_i \bar{x})'S^{-1}(x_i \bar{x})$.
 - Examine these distances for unusually large values.
 - In a *chi-square* plot, these would be the points farthest form the origin.

Figure 4.11 (Page 191)

Transformations to Near Normality I

- If normality assumption is violated
 - Transform the data
 - For example:
 - Count data (y) take the square roots (\sqrt{y})
 - Proportion data (p) take logit transformation $\left(\frac{1}{2}\log\frac{p}{1-p}\right)$
 - Correlation coefficients (r) take Fisher's z-transform $\left(\frac{1}{2}\log\frac{1+r}{1-r}\right)$

Transformations to Near Normality II

- It is convenient to let the data suggest a transformation
 - A useful transformation for this purpose is the family of power transformations
 - For positive r.v.
 - Shrinking ..., x^{-1} , $x^{-1/2}$, $\ln x$, $x^{1/4}$, $x^{1/2}$
 - Expanding x^2, x^3, \dots

Transformations to Near Normality III

Box and Cox family of power transformations

$$x^{(\lambda)} = \begin{cases} \frac{x^{\lambda} - 1}{\lambda}, & \text{if } \lambda \neq 0\\ \ln x, & \text{if } \lambda = 0, \end{cases}$$

Transformations to Near Normality IV

• Choice of an appropriate power λ is the solution of that maximizes the expression

$$I(\lambda) = -\frac{n}{2} \ln \left[\frac{1}{n} \sum_{j=1}^{n} \left(x_j^{(\lambda)} - x_j^{\overline{(\lambda)}} \right)^2 \right] + (\lambda - 1) \sum_{j=1}^{n} \ln x_j.$$

 After the transformation, one should also check for adequacy of normality.

Example 4.16 (Page 194)

Transformations to Near Normality V

- Multivariate Data:- Try to make each marginal distribution approximately normal.
 - For all k in $1, \ldots, p$ maximize

$$I_k(\lambda) = -\frac{n}{2} \ln \left[\frac{1}{n} \sum_{j=1}^n \left(x_{jk}^{(\lambda_k)} - x_{jk}^{(\bar{\lambda}_k)} \right)^2 \right] + (\lambda_k - 1) \sum_{j=1}^n \ln x_{jk}.$$

- Hence, $\hat{\lambda} = [\hat{\lambda}_1, \dots, \hat{\lambda}_p]$.
- Therefore, the *j*th transformed multivariate observation is

$$x_j^{(\hat{\lambda})} = \left[\frac{x_{j1}^{\hat{\lambda}_1} - 1}{\hat{\lambda}_1}, \dots, \frac{x_{jp}^{\hat{\lambda}_p} - 1}{\hat{\lambda}_p}\right]'.$$

• It's equivalent to maximizing the univariate likelihood for kth feature over the parameters μ_k , σ_{kk} and λ_k .

Transformations to Near Normality VI

• If the normal marginals are not sufficient to ensure that the joint distribution is normal, one can start with initial values as $\lambda = [\hat{\lambda}_1, \dots, \hat{\lambda}_p]$ to maximize the multivariate function

$$I(\lambda_1,\ldots,\lambda_p) = -\frac{n}{2}\ln|S(\lambda)| + \sum_{k=1}^p \left((\lambda_k - 1)\sum_{j=1}^n \ln x_{jk}\right),\,$$

where $S(\lambda)$ is the sample covariance matrix computed from $x_j^{(\lambda)} = [\frac{x_{j1}^{\lambda_1} - 1}{\lambda_1}, \dots, \frac{x_{jp}^{\lambda_p} - 1}{\lambda_p}]'$.

• It's equivalent to maximizing the multivariate likelihood over the parameters μ, Σ and λ .
